

A convenient practice is to make

$$s = \frac{1}{2\pi} \text{ cm} = 1,59 \text{ mm, whereby } \varrho = \frac{V}{I} \text{ cm.}$$

B.2) Different Probe Distances (fig. 4).

$$\varrho = G \frac{V}{I}$$

$$\text{where } G = \frac{2\pi}{\frac{1}{s_{12}} + \frac{1}{s_{34}} - \frac{1}{s_{12} + s_{23}} - \frac{1}{s_{23} + s_{34}}} ; \quad (6)$$

From equation (6) one can calculate the change in G caused by small probe displacements from their nominal locations (b).

Figure 5:

Probe displacements from equal distances.

For equi-distant probes (figure 5), the result is to a first approximation:

$$G = \frac{2\pi s}{1 + \frac{3 \cdot \Delta_1}{4s} - \frac{5 \cdot \Delta_2}{4s} + \frac{5 \cdot \Delta_3}{4s} - \frac{3 \cdot \Delta_4}{4s}} , \quad (7)$$
